Announcements

- Reading Chapter 18 (Security)
- Review Session for the final
  - Wed 5/12 (Study day) 10-11:30
- Project #6 is on the web
  - It is a continuation of #5 and requires your #5 to work

Project #6 Notes

- Uid
  - First process has uid of 0
  - Spawned processes
    - Inherit uid of parent
    - Unless setuid bit is set on program to run, then the uid of the owner of that file is used
- ACLs
  - First ACL entry is owner
  - Others are for other users
    - Can delete these entires with setACl(file, uid, 0)
  - Uid 0 can open any file regardless of ACLs

Authentication (cont.)

- How does a user know what computer they are using?
- Need to have *mutual authentication*
  - computer presents some information that only it could contain
  - example: Windows <ctrl>-<alt>-<del> to login
    - user software can't trap that information
    - assumes that the kernel itself is secure
- telephone example:
  - never give banking/credit card info over the phone unless you placed the phone call
    - i.e. you use the telco namespace for authentication

Example (UNIX passwords)

- use a function that is hard to invert
  - "easy" to compute f(x) given x
  - hard to compute x given f(x)
  - the function used is a variation on the DES or MD5 algorithms
    - changes selected items in the transformation matrix to prevent hardware attacks
  - store only f(x) in the filesystem
- to login:
  - user supplies a password x'
  - compute f(x') and compare to f(x)
- salt
  - add an extra two characters to x so that the same x will produce different values on different machines
  - need to store salt along with password
- dictionary attach
  - if its to easy to compute f(x)
  - can "guess" many passwords and try them out
  - salt makes this much harder

Types of Software Threats (Malware)

- Trojan Horse
  - a program that looks like a normal program
  - for example a login program written by a user
  - UNIX example: never put "." early in your path
- Trap door
  - hole left by the programmers to let them into the system
  - "system" password set to a default value by the vendor
- Worms
  - programs that clone themselves and use resources
  - Internet worm:
    - exploited several bugs and "features" in UNIX
      - .rhosts files
      - bug in finger command (overwrite strings)
      - sendmail "debug" mode to run commands

Viruses

- Most common on systems with little security
  - easy to write to boot blocks, system software
  - never run untrusted software with special privileges
  - Don’t perform daily operations with root/system privileges
- Possible to write system independent viruses
  - MS Word virus
    - uses macros to call into the OS
  - HTML (javascript)
  - Flash

Access Matrix

- Abstraction of protection for objects in a system.
  - Rows are domains (users or groups of users)
  - Columns are objects (files, printers, etc.)
  - Items are methods permitted by a domain on an objects
    - read, write, execute, print, delete, …
- Representing the Table
  - simple representation (dense matrix) is large
  - sparse representation possible: each non-zero in the matrix
  - observation: same column used frequently
    - represent groups of users with a name and just store that
  - create a default policy for some objects without a value
- Revocation of access
  - when are access rights checked?
  - selective revocation vs. global

Access Matrix

	F1	F2	F3	Laser Printer	
D1	read		execute		
D2			execute	print	
D3	read, write		execute		
D4			execute		
D5		delete			

- Rows represent users or groups of users
- Columns represent files, printers, etc.

Capabilities

- Un-forgeable Key to access something
- Implementation: a string
  - I.e. a long numeric sequence for a copier)
- Implementation: A protected memory region
    - tag memory (or procedures) with access rights
      - example - x86 call gate abstraction
    - permit rights amplification
