Accessible Abstract: Often, the questions users ask search engines or chatbots aren't perfect: they have errors, are vague, or lack context. Humans are able to deftly navigate these issues, but computers still struggle. We analyze the differences in how humans and computers repair imperfect questions to suggest how to improve AI's question answering abilities.

Abstract

Questions help unlock information to satisfy users' information needs. However, when the question is poorly posed, answerers (whether human or computer) may struggle to answer the question in a way that satisfies the asker, despite possibly knowing everything necessary to address the asker's latent information need. Using Reddit question-answer interactions from r/NoStupidQuestions, we develop a computational framework grounded in linguistic theory to study poorly-posedness of questions by generating spaces of potential interpretations of questions and computing distributions over these spaces based on interpretations chosen by both human answerers in the Reddit question thread, as well as by a suite of large language models. Both humans and models struggle to converge on dominant interpretations when faced with poorly posed questions, but employ different strategies: humans focus on specific interpretations through question negotiation, while models attempt comprehensive coverage by addressing many interpretations simultaneously.

1 Introduction

When an AI system is presented with a question by a user, it has an onus to answer. Sometimes, when information-seeking users know little about the topic they are asking about, the questions they present to the system are flawed. For example, the question "How many universities are located in Cambridge?" presents an ambiguity, as Cambridge, USA and Cambridge, England are both valid interpretations of the entity Cambridge in the question (Min et al., 2020; Stelmakh et al., 2022). Questions may also be flawed due to false presuppositions, as in the question "Who is the king of France?" (Kim et al., 2021; Yu et al., 2023). Ambiguity, false presupposition, and other such phenomena in questions are not new issues in NLP research (Section 7). However, rather than approaching each

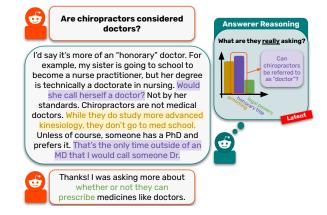

Figure 1: An *interaction* involving a poorly-posed question. After reasoning about the intent of the question, the answerer addresses two possible interpretations, but their answer did not satisfy the asker's information need.

failure mode of questions independently, we provide a theoretical foundation to understand how imperfect questions are answered by humans and machines alike.

Consider the interaction in Figure 1, taken from the Reddit community r/NoStupidQuestions. The asker (in orange) asks "Are chiropractors considered doctors" in an attempt to articulate an information need. This need may have arisen from a variety of situations: perhaps the asker wants to know whether they should refer to their chiropractor as "Dr." or maybe they are wondering if chiropractors undergo similar training as doctors. However, as written, it is difficult to identify the asker's particular information need (Taylor, 1962), and in turn, determine the resolution conditions (Ciardelli et al., 2021) of their question. The space of interpretations of their question includes those about chiropractor schooling, title, or legal powers as compared to doctors, among others.

Humans often reason about the intent of conversational participants to smooth communication with others (Grice, 1975). When a hearer successfully reconstructs a speaker's intent and responds appropriately, the communication can be considered as successful (Haugh, 2008). In question answering, this can include reasoning about *why* a speaker posed a question or reasoning about probable interpretations of a question. As pictured in Figure 1, the answerer tries to reason about the asker's information need, ultimately selecting an interpretation and answering it, but as pictured, their chosen interpretation does not align with the asker's original need.

This interaction highlights the central concern of this work: what makes a particular expression of an information need *poorly posed*? How do humans fare when reconstructing information needs of askers from questions, and how does their behavior differ from model behavior on such questions?

We begin by providing theoretical structure to poorly-posed questions (\S^2) based on the linguistic theory of inquisitive semantics (Ciardelli et al., 2021), defining a poorly-posed question as one where-despite engaging in pragmatic reasoninganswerers cannot determine the asker's information need, struggling to identify a probable interpretation. We collect questions¹ from the Reddit community r/NoStupidQuestions, focusing on QA interactions consisting of a question, answer, and a reply to the answer containing feedback on whether their information need was met $(\S3)$. Expert linguists annotate these interactions to identify interpretations chosen by answerers. We generate spaces of possible interpretations (§4) over which we induce a distribution representing the interpretations chosen by answerers (§5), and use this distribution to identify when a question is poorly posed. Lastly, we compare human and model behavior when answering poorly-posed questions $(\S6)$, studying cases when they converge or diverge on interpretations. We find that while humans adopt a precision-oriented strategy, engaging in question negotiation when answering poorly posed questions, models are recall-oriented.

2 What makes a question poorly posed?

Cooperative communication between humans hinges on our ability to draw inferences from the utterances of our conversational partners to identify their underlying intention or goal (Goodman and Frank, 2016). The space of possible interpretations or inferences one may draw from an utterance is not only large, but depends on conversational and contextual factors. Humans effortlessly engage in such reasoning processes daily. However, interactions may go awry when they cannot draw intended inferences or correctly identify a speaker's intended interpretation.

When answerers' attempts to answer a question cannot easily identify the intended interpretation, this may signal a poorly posed question. We describe our theoretical framework for analyzing questions, drawing on foundational work from information retrieval and theoretical linguistics to present our definition of a poorly posed information-seeking question.

The Process of Asking a Question. When someone wants to know something (an information need), they often ask a question. At times, this latent information need becomes distorted or muddled as the asker translates it into a question directed at another human or a QA system. Taylor (1962) formalizes this by describing four distinct stages of question formulation. Users start with an unexpressed need (the visceral need) for information, arising from some dissatisfaction. As they progress towards expressing this need, they may identify a description-possibly nebulous-of their dissatisfaction (the conscious need), but such a description may be rife with issues since they do not know much about what they are asking about. The user may continue to formalize their need as a question, ideally a more careful, clearer formulation with less ambiguity (the formalized need). Lastly, they may *reformulate* their question in the previous stage, taking into account whom it will be asked of (the compromised need): for example, if asking a search engine like Google, they may distill their question into keywords.

In practice, users may decide to ask their question to a QA system or a human **at any point throughout this process.** The burden then falls on agents answering the question to reconstruct the asker's latent information need to provide a helpful answer. This is easy when the user has the appropriate knowledge to formulate their question *and* interpret a response (Miyake and Norman, 1979). In other cases, this reconstruction can prove difficult, and the answerer may fail to reconstruct the asker's information need. We consider a question **poorly posed if**, *even after an answerer's additional reasoning*, they are unable to identify, and in turn address, the asker's visceral or conscious

¹Code and data available at https://github.com/ nehasrikn/poorly-posed-questions.

information need. This reasoning could involve computing a distribution over interpretations of the question (§5) or identifying and correcting false presuppositions (Yu et al., 2023).

Question Semantics. Another way to characterize a poorly posed question is using *resolution conditions* (Ciardelli et al., 2021). Classical accounts of semantics derive the meaning of statements by *truth conditions* (Heim and Kratzer, 1998). The semantic content of a sentence, or its *proposition*, represents the set of all worlds where the statement is true. However, it is difficult to analyze questions using these accounts, since questions are *inquiring* about the state of the world.

The framework of *inquisitive semantics* (Ciardelli, 2018) argues that question understanding is predicated on knowing what information is needed to resolve it (Ciardelli, 2017). An information state s, or a set of possible worlds that are compatible with the information s encodes, supports a question Q if the information in s resolves Q. Analogous to a proposition expressed by a statement, the *issue* expressed by a question is the set of information states that support it. We draw on this framework to help define a poorly-posed question.

A question may be poorly posed if, as phrased, it is impossible to identify *what* information is needed to resolve it. Note that this does not commit to the *content* of the information.² For example, consider the question "*Can literature not be about humans*?" There are many different interpretations of this question, each with different supporting information states, or sets of worlds where information holds true that would resolve the question, as in the two example interpretations below:

[Interpretation 1: "What is the criteria for a piece of text to be considered "literature" in the colloquial sense?"] Some example information states that may satisfy this interpretation include: (s_1) The set of worlds in which literature is defined by its artistic quality. A piece of text is considered "literature" if it demonstrates creativity, aesthetic, value, and artistic merit. (s_2) The set of worlds in which literature is defined by cultural or historical significance. (s_3) The set of worlds in which literature is defined by its ability to provoke thought or evoke emotion.

[Interpretation 2: "Can central characters in literature be non-human, such as animals?"] Some example information states that may satisfy this interpretation include: (s_1) TThe set of worlds in which all central characters in literature must be human. (s_2) The set of worlds in which non-human central characters are allowed, but only if they are anthropomorphized. (s_3) The set of worlds in which central characters in literature can be non-human, but only in specific genres.

An answer to the original question may include information encoded by any of the states described above, and *it is not necessary to know the answer to the question to identify which information states will resolve it.* However, we cannot clearly identify *which* information states resolve this original question, since there are many interpretations of the original question, a defining characteristic of poorly-posed questions.

Definition. Drawing on the groundwork above, we consider a question poorly posed if, even after an answerer engages in pragmatic reasoning (Grice, 1975) about an asker's information need, they cannot identify a dominant interpretation of the question. This is not only a function of the asker's utterance alone, but a combination of their underlying information need *and* their chosen utterance. It is not the presence of required reasoning by an answerer that makes a question poorly-posed, but rather that reasoning does not *bias* an answerer towards a particular set of resolution conditions.

3 Collecting Poorly-Posed Questions

Many QA datasets are collections of questions paired with gold answers (Rogers et al., 2023; Rodriguez and Boyd-Graber, 2021). From these pairs alone, it is not only difficult to understand the reasoning answerers engaged in when answering a question, but also *whether the answer satisfied the original asker's information need*, a crucial part of improving QA: understanding what types of question interpretations, answerer reasoning, and dialog moves satisfy asker information needs can help inform QA systems faced with poorly-posed information-seeking questions.

We construct a dataset of information-seeking interactions between Reddit³ users, and introduce an annotation scheme designed to capture the latent reasoning answerers perform when answering a question. Our final dataset contains 500 questions annotated by expert linguists.

3.1 Question Selection

To maximize the ecological validity of our study, the questions we choose reflect organic instances of information-seeking interactions. We source

²Poorly-posed questions are distinct from *open-ended questions*, those that are not answerable with a "yes" or "no." See Appendix A for more discussion.

³www.reddit.com

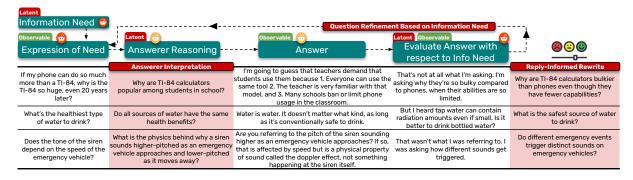

Figure 2: Example interactions through the question life cycle. Askers express latent information needs through questions to answerers who reason about those needs when answering. Askers then evaluate the answer with respect to their original information need, refine their question, and proceed through the cycle again. We intervene to collect answerer interpretations (Stage 1) and reply-informed rewrites (Stage 2) to study this cycle.

our dataset from r/NoStupidQuestions, a popular Subreddit where users ask questions about any topic at any level, even if their questions are not fully formed (Appendix B). As such, these questions span all stages of the asking process (Figure 2). Unlike factoid QA datasets such as Natural Questions (Kwiatkowski et al., 2019), questions in r/NoStupidQuestions are complex and openended, requiring long-form answers (Fan et al., 2019) with background information, examples, anecdotes, or analogies.

After filtering posts using a set of heuristics (Appendix C), we leverage the thread structure of Reddit by identifying **interactions**, or tuples of (question, answer, reply) where (1) a question (Q) is a post by a user to r/NoStupidQuestions; (2) an answer (A) is an individual top-level comment responding to the post which contains an answer to the question; and (3) a reply (R) is a comment from the original asker addressing answer. Collecting these interactions helps determine whether an answerer correctly interpreted the original question, as well as a more refined formulation of the asker's original information need.

Question authors may confirm their need was **met** (*That's exactly what I was looking for!*), **not met** (*"That was not what I meant"*), or provide **no useful feedback** (e.g reacting to a joke). To identify when askers do convey direct feedback, we elicit few-shot judgments from 11ama-3-8b-instruct (Dubey et al., 2024) on replies (*R*). For each reply *R* on posts that survived filtering, the model performs a three-way classification: (1) *R* indicates that an information need was met, (2) not met, or (3) not determinable.

We identify the subset of 142,878 comments

from filtered posts containing Rs (just 7% of all comments), and elicit judgments with Prompt C.1 on Rs using eighteen manually selected in-context examples split evenly across the three labels. The majority of Rs lack clear feedback: only 11.9% as indicate an information need was met and 9.4% indicate a need was not met. These judgments surface higher quality data that we then ask expert linguists to annotate.

3.2 Annotating QA Interactions

One of our primary goals is to analyze the relationship between an asker's question Q and their underlying information need. Their reply R to an answer A gives us additional insight into their original need by correcting certain assumptions made by an answer, including feedback on the particular interpretation chosen by an answerer. We recruit seven expert linguists from Upwork⁴ to annotate 500 (Q, A, R) interactions, separating them into two groups for two stages of annotation.

Sampling Instances for Annotation. Using the judgments we elicited from 11ama-3-8b-instruct on asker replies (§3.1), we sample 400 (Q, A, R) interactions with an unmet information need and 100 interactions of a satisfied information need. Annotating both types of interactions allows us to study why questions lead to satisfactory or dissatisfactory answers.

Stage 1: Reconstructing Answerer Interpretations. Answerers make inferences about what askers are *intending* to ask or what askers are assuming. They then answer according to *their* interpretation of the asker's question. Sometimes this

 $^{^4}Annotators are paid $15/hr on Upwork (www.upwork.com).$

interpretation is close to what the asker intended, and sometimes it is not. For example, the vague question asked in Row 1 of Figure 2 about why TI-84 calculators are so "huge" (Column 1) was interpreted by the answerer (Column 3) to mean "popular". The first group (four annotators) reconstruct the interpretation answered in A (Column 2, Figure 2) from *only* Q and A (not R), with the option to indicate no change if there was strong alignment between the original question and the answerer's interpretation of the question. They do not select from generated interpretations, but write from scratch to remain unbiased (full annotator instructions in Appendix D). Two annotators annotate each example.

Stage 2: Reply-Informed Question Reformulation Next, the second group of three annotators use all three components of the interaction (Q, A, R) to rewrite Q to capture the intent or additional information expressed in R (Column 4, Figure 2) when R indicated an unmet information need (Column 5). Replies help us understand whether the interpretations adopted by answerers that annotators identify in Stage 1 matched the asker's original information need. In the interaction in Row 1 of Figure 2, we learn from their reply (Column 4) that by "huge", the asker wanted to understand why TI-84 calculators are so bulky, instead of "popular" as interpreted in A (Column 3). Annotators were instructed to eliminate any ambiguity, underspecificity, or vagueness in the original question. In some cases, annotator rewrites based on the asker reply were not answerable by the answer provided, since, in many cases, the answerer answered a different question than what the original poster intended. Again, two annotators annotate each example.

4 Question Interpretations

Poorly-posed questions often prevent answerers despite reasoning about the asker's intent—from reliably identifying a dominant interpretation (or set of interpretations) to address, making it difficult to satisfy the user's needs. If many answerers attempt to determine the resolution conditions of the question, but arrive at different interpretations, this may signal that the asker's information need was unclear. Conversely, answers *converging* on a particular interpretation *en masse* may indicate that a user's information need was easily recoverable. Identifying likely interpretations of a question is the first step in building a distribution of which interpretations answerers choose.

We generate potential interpretations I of questions, or fine-grained natural language questions that capture a particular facet of the question. By definition, they must be free of ambiguity, vague, or underspecified language and their resolution conditions must be easily identifiable.⁵ These interpretations $I_1...I_n$ form a *space* (S_I) of valid interpretations of the question representing the range of plausible meanings that reasonable answerers might derive from the original question.

Interpretation Generation. We prompt gpt-40 and gemma-9b to generate interpretations for each original question.⁶ Models are only provided the question with no other context and are instructed to generate a variable number of interpretations in a zero-shot manner using Prompt D.1. Using models of different sizes and capacities allows for a wider range of interpretations that better cover the space.

Deduplicating Interpretations. Generated interpretations may be overlapping. For example, "Why don't cashiers sit in chairs when they perform their job?" overlaps with the interpretation "Why do cashiers perform their job standing?", since they share a subset of resolution conditions (\S 2). We deduplicate the set union of generated interpretations to form a set of *unique* interpretations, or the "space" of interpretations (S_I) we consider for each question (Table 2) for use downstream. To deduplicate generated interpretations, we embed each I using NV-Embed-7B (Lee et al., 2024) and then compute pairwise cosine similarity between all interpretations (Instruction D.2). We then construct a graph G where nodes are generated interpretations $I_1...I_n$ and edges $e(I_i, I_j)$ are drawn between interpretations with cosine similarity above $\theta = 0.85$. Maximal cliques of G (Tomita et al., 2006) then contain sets of highly similar or equivalent interpretations. We select clique representatives by choosing the interpretation least similar to other members, and together, these representatives form S_I . If an interpretation I is a member of multiple cliques, we assign it exclusively to its "strongest" clique by way of average similarity of clique nodes.

⁵In practice, though some ambiguity may remain, most interpretations have clearer resolution conditions than original questions. Paraphrases or short clauses from original questions are not valid interpretations.

⁶Specifically, gpt-4o-2024-08-06 and gemma-2-9b. We experimented with many models, but found high overlap between interpretations generated by open-source models.

Validating Interpretations. To assess the *sound*ness of interpretations, we randomly sample 100 (Q, I_n) pairs, and ask two external annotators to judge whether or not I_n reasonably follows from question Q.⁷ Annotators judge 76% of interpretations as sound, with a Cohen's Kappa of $\kappa = 0.7$.

To assess coverage and alignment with humangenerated interpretations, we ask a team of six undergraduate Quiz Bowl players⁸ to collaboratively enumerate interpretations on a random sample of 30 questions. Then, an author manually matched student-written interpretations with model-generated interpretations. On average, 78% of human-written interpretations were present in the generated interpretation space per question. Qualitatively, human interpretations tended to use less precise language than model-generated interpretations, sometimes propagating issues from original questions (Appendix E). Models include a higher number of interpretations per question, typically a superset of human interpretations. We elect to use model interpretations for replicability, scalability, and higher coverage.

5 Identifying Poorly-Posed Questions from Question-Answer Threads

Section 2 defines poorly-posed questions as those where answerers struggle to identify the asker's information need despite attempting to reason about their intent. We operationalize this computationally by analyzing *many* answerers' responses to each question in our dataset. We identify which interpretation(s) from S_I each top-level commenter adopts on the question's Reddit post and examine the distribution of chosen interpretations. Convergence on one or few interpretations suggests a well-posed question, while high disagreement indicates poor posedness—answerers cannot reliably recover the asker's intended information need.

5.1 Measuring Poorly-Posedness from Interpretation Distributions

Interpretation Matching. An answer A (here, a comment) *adopts* interpretation I if it contains the information necessary to answer I. Since it is impossible to obtain ground truth on an answerer's

chosen interpretation, this approximates their reasoning about what to address in their answer. This formulation also allows for an answer to match with multiple interpretations if it contains information addressing more than one.

We use an extractive QA setup to match answers with interpretations. For each comment A in the question's corresponding Reddit thread, we consider each I in the interpretation space S_I , instructing a model to extract a span from the comment that supports I. If it cannot find a supporting span addressing a particular interpretation, the model is instructed to abstain from answering. We use three in-context examples along with Instruction D.3 to match interpretations to human comments using flan-t5-xx1 (Chung et al., 2024). Using a relatively weaker QA model ensures fewer false positives when direct evidence is *not* present in an answer to support an interpretation.

We validate this matching by sampling 100 (I, A, span) judgments and judging whether the span identified by the model indeed supported I. 87% of the judgments from flan-t5-xxl were valid as annotated by an author, with a Cohen's Kappa of k = 0.82 with an external annotator.

Computing a Distribution over Interpretations. Using this method, we construct an interpretationcomment matrix M for each question's Reddit thread, where row i represents the ith interpretation in S_I , column j represents a top-level comment, and entry (i, j) is 1 if the model determines comment i supports interpretation i and 0 otherwise. To represent consensus, we multiply column j by the number of upvotes comment j receives, ensuring widely chosen interpretations are well-represented.⁹ We construct the chosen interpretation distribution by summing along rows in M to compute each interpretation's net support across all comments and applying softmax, resulting in a distribution that approximates chosen answerer interpretations across S_I .

Measuring Poorly-Posedness. In line with our definition and intuition from §2, we want to compute a scalar score from these distributions in a way that assigns a low score when most of the mass is concentrated around a small number of interpretations (ideally one), indicating well-posedness, and a high score when that mass is more diffused

⁷The annotators were provided no other context beyond the question and interpretation, nor were they told whether the interpretation was generated by a model or human.

⁸Quiz Bowl (Jennings, 2006) is a trivia competition designed to test knowledge on many topics including history, literature, and science.

⁹For example, if an answer receives 4 upvotes, the cells in M for that answer's interpretation(s) change from 1 to 4.

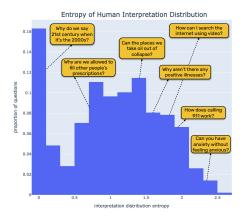

Figure 3: Entropy of human interpretation distributions. High entropy indicates a question is poorly posed.

(poorly-posedness). While there are many potential functions to achieve this, we choose to compute the *entropy* (Shannon, 1948) of the distribution, which **approximates how uncertain humans were in identifying the question asker's information need.** *Low* entropy indicates a dominant interpretation that humans chose to address in an answer, while *high* entropy signals difficulty in deciding the original question's resolution conditions, indicating a poorly-posed question.

To validate that this method meaningfully approximates poorly-posedness, we select the fifty questions with the lowest entropy interpretation distributions (LOW-ENTROPY) and the fifty questions with the highest entropy (HIGH-ENTROPY). Two native English speakers score each interpretation I in S_I on a 1–5 scale indicating the likelihood that I aligns with the question asker's information need This study controls for platform-specific factors that may influence inducing an interpretation distribution from comments in a thread.¹⁰ Annotators received only the question and S_I , the interpretation space. Their judgments are positively correlated (Spearman's $\rho = 0.57$).

For each question, we apply softmax to the distribution of annotator scores for all interpretations and compute its entropy (Appendix F). A two-sample *t*-test on the difference of mean entropy of *annotator distributions* between THREAD-LOW-ENTROPY and THREAD-HIGH-ENTROPY reveals that THREAD-HIGH-ENTROPY has higher mean entropy than THREAD-LOW-ENTROPY for both annotators (p < 0.001). These results validate our computational approach for estimating poorly-

posedness using the *distribution* of chosen interpretations of human answers in the Reddit thread.

5.2 Asker Replies and Poorly-Posed Questions

Aside from studying aggregate interpretation distributions from threads (constructed only from questions Q and sets of answers A), we also explore the relationship between asker replies R and questions identified as poorly posed by our method, specifically analyzing cases where askers indicate that their information need was met on high entropy (poorly-posed) questions.

Asker replies are more likely when questions are poorly posed. There is a statistically significant positive Pearson correlation ($\rho = 0.44$, p < 0.0001) between the entropy of the thread interpretation distribution and the proportion of comments that receive asker feedback. This indicates that question askers are likely early in the question asking process (Figure 2) and are attempting to define their conscious or formalized information need by engaging with answerers.

Asker replies are more likely to be positive when the question is poorly posed. Questions with entropy greater than one standard deviation above the mean entropy of all questions in our dataset have a greater likelihood of replying indicating that their information need was met than in questions with entropy less than one standard deviation below the mean. In these cases, answers are more packed with more information or reveal interesting information that the asker had not considered. For example, an answer to the question "What is the resting position of the tongue?" related it to the native language of a speaker, an interpretation that the asker had not considered nor was included in our generated interpretation space S_I .

Non-dominant interpretations are more likely to receive positive asker replies when the question is poorly-posed. Overall, when a comment Ahas a reply R, it is more likely to support a *nondominant* interpretation (Figure 6)—interpretations with lower likelihood in the softmax distribution. When entropy is high (greater than one standard deviation from the mean), asker replies to comments addressing non-dominant interpretations are 11% more likely to signal the satisfaction of an information need than in questions with low entropy (lower than one standard deviation from the mean), indicating that answerers strayed from popular in-

¹⁰For example, the point in time that an answerer responds may affect the interpretation they choose since they may read comments posted earlier.

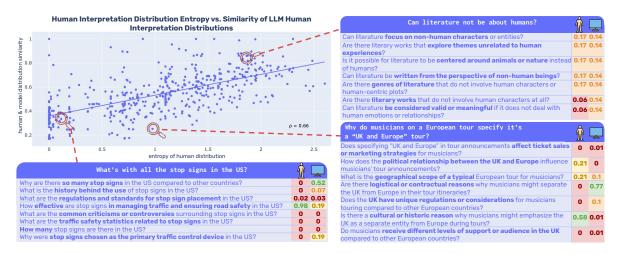

Figure 4: Entropy of human interpretation distributions plotted against the similarity of human and model interpretation distributions (1 - Jensen-Shannon distance). Humans and models struggle to converge on interpretations for poorly-posed questions with high entropy. Example callouts include both interpretation distributions.

terpretations and likely deeply reasoned to arrive at a lower-likelihood interpretation.

Reply-informed rewrites are semantically further away from dominant interpretations than original questions. Refined questions based on asker replies R are always semantically further away from dominant interpretations than original questions were, as measured by similarity of embeddings produced by NV-Embed-2 (Figure 8). Interestingly, the reply-informed rewrite remains closer to the dominant interpretation in poorly posed questions than in other questions, underscoring the influence of answerers when users are still defining their exact information need.¹¹

6 Contrasting Human and Machine Answers

Comparing human and model behavior in response to poorly-posed questions can help identify opportunities for improved alignment and inform the design of benchmarks that include poorly-posed questions. We experiment with computing distributions over interpretations chosen by a suite of LLMs on questions in our dataset to study divergences in crowdsourced human and model interpretations.

Experimental Setup. We include 12 instructiontuned models of various sizes and configurations, including proprietary and open source models: 2B and 9B gemma-2-instruct (Team et al., 2024), 8B and 70B llama-3-instruct (Dubey et al., 2024), 2B and 8B granite-3.0-instruct (Granite Team, 2024), phi-3.5-mini-instruct and Phi-3-medium-128k-instruct (Abdin et al., ministral-8b-instruct-2410 (Mis-2024), tral AI, 2024), athene-v2-chat (Nexus-Flow, 2024), gpt-4o-mini-2024-07-18, and gpt-4o-2024-08-06 (OpenAI, 2024). Models are prompted to respond in five sentences or less (Prompt D.4) in a zero-shot setup with greedy decoding, indirectly forcing them to adopt their likely interpretations instead of hedging or providing a deluge of information. We do not judge *accuracy* of answers since we decouple question *interpretation* from question *answering*.

We construct an interpretation-model answer matrix M by using the same interpretation matching method used for human comments (§5) and compute a *model* interpretation distribution by summing across rows in M and applying softmax.

Models, like humans, produce high entropy interpretation distributions on poorly-posed questions. We plot human interpretation distribution entropy (capturing question poorly-posedness) against human-model (h_i and m_i , respectively) distribution similarity (Figure 4) as measured by $1 - d(h_i, m_i)$ where d is the Jensen-Shannon distance between m_i and h_i . When questions were poorly posed (high human entropy), model answers were also distributed across the interpretation space S_I (e.g. Can literature not be about humans?). This high entropy pattern can flag questions in benchmarks where models or humans fail to converge on interpretations, indicating poor posedness.

¹¹This is exemplified by the interaction: **[Asker]** Can literature be not about humans? **[Answerer]** Are you asking if human beings are capable of writing biology textbooks? **[Asker Reply]** I think I'm asking if biology textbooks can be literature, but I'm not sure myself...

Table 1: Models take a recall-oriented approach to questions, addressing significant portions of the interpretation space in a single answer.

When they do converge, models and humans converge on different interpretations. The entropy of human interpretation distributions is correlated with model interpretation distributions (Figure 7). However, when humans converge, models tend to either converge on a different interpretation (Figure 4, lower left) or remain spread out over interpretations. When answering questions, humans reason about the intent, goal, or reason behind the question, ultimately affecting which interpretations they may choose to address. For example, the dominant selected interpretation of "Why can't I get drunk?" by humans was "Am I consuming alcohol in a way that does not lead to intoxication?", while models addressed interpretations related to the legal drinking age or medications that may interact with alcohol. It is unclear that models holistically consider the reason behind a question during QA to bias their response towards likely interpretations. Future multiturn QA datasets that include asker feedback on their information need may help produce well-aligned systems that engage in question negotiation to better pinpoint user need.

Models are recall-oriented answerers. In 84% of questions, the set of interpretations addressed by all models was a superset of those addressed by all humans. Investigating further, we compute the average proportion of the interpretation space S_I addressed by each model's responses across all questions in our dataset (Table 1): specifically, for each question, we divide the number of interpretations by each model adopted by $|S_I|$ to understand how comprehensive an average model answer is. gpt-4o-mini narrowly emerged as the model addressing the largest portion of S_I for questions (Table 1). We compute this metric for human an-

swer threads as well to compare whether humans or models tend to address more interpretations per individual response. On average, individual human answerers addressed 44% of the interpretation space in an answer, while models addressed 77%. In doing so, models do tend to include at least *some* information targeting the dominant interpretation converged on by humans, but are "recalloriented" with respect to the interpretation space, because they simply address a higher proportion of the space in an answer, in an attempt to satisfy the asker. This may be an artifact of human-AI alignment techniques that are based on human satisfaction with an answer.

7 Related Work

Many studies focus on a specific failure mode of questions, such as ambiguity (Min et al., 2020; Stelmakh et al., 2022; Cole et al., 2023; Piryani et al., 2024) or false presupposition (Yu et al., 2023; Kim et al., 2021, 2023; Hu et al., 2023; Kaur et al., 2024). Others study *unanswerable* questions with respect to a document (Zhao et al., 2024; Rajpurkar et al., 2018). While our dataset contains questions presenting issues studied in these works, we present a *unified* definition of poorly-posed questions, abstracting away specific failure modes and focusing on *information need*.

Pragmatic reasoning in QA is a relatively understudied area. Some study reasoning about speaker intent by constraining the domain (Wahlster et al., 1983) such that speakers share all referents (Fried et al., 2017). Qi et al. (2023) collect a dataset involving reasoning about speaker intent during QA, but their dataset *simulates* information-seeking interactions. In contrast, we study naturallyoccurring interactions where users themselves are in the processing of defining questions for greater ecological validity (De Vries et al., 2020).

8 Conclusion

Questions are not perfect. The tools developed in this paper help diagnose imperfect evaluations both during dataset curation and *ex post facto*. The contributions of this paper help detect problems that make questions less than perfect. Making the discourse moves that can lead to satisfying resolutions can make our interactions with AI more natural and successful while also improving our understanding of the subtle give and take two interlocutors engage in when answering an imperfect question.

Acknowledgments

We thank the anonymous reviewers as well as the members of the University of Maryland CLIP lab for their thoughtful feedback. We also thank our annotators: expert linguists from Upwork, as well as Maya Srikanth and Rupak Sarkar. This work was supported by NIH Award No. R01MD016037 (Srikanth and Boyd-Graber) and NSF CAREER Award No. 2339746 (Rudinger). The content is solely the responsibility of the authors and does not necessarily represent the official views of the National Institutes of Health or the National Science Foundation. The funders had no role in study design, data collection and analysis, decision to publish, or preparation of the paper.

Limitations

This work studies QA interactions Reddit, an online community forum. We induce distributions of human interpretations to better understand how human answerers deal with poorly-posed questions. Unlike studies that simulate such interactions, we do not have access to the reasoning conducted by original askers or answerers, using their text to derive signal retrospectively.

We also do not use the post body of Reddit posts as additional context in our experiments. Some posts have no text in their body and some have large paragraphs. To ensure a level playing field across all questions, we opt not to use the added context in posts where it is available. Future work may consider ways to incorporate the body of the post to bias the interpretation space generation or selection of likely dominant interpretations by humans.

Comment Thread Length

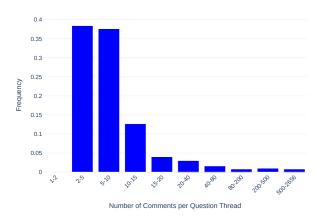

Figure 5: Distribution of thread length of posts in our dataset. Most posts we study contain 2–10 comments.

Interpretations from Comments with Asker Feedback

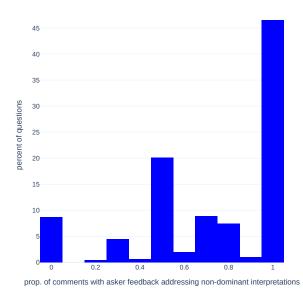

Figure 6: Most comments with asker feedback address a non-dominant interpretation of the original question.

A Open-Ended Questions

Open-ended questions are those that cannot be answered with binary "yes" or "no", often requiring in-depth long form answers (Chakrabarty et al., 2022). This is distinct from poorly-posedness. We consider poorly-posed questions as those where answerers cannot identify a dominant interpretation of the question and in turn, what information or commentary is needed to satisfy the asker. See Table 3 for examples of open-ended questions that are poorly-posed and vice versa. Both questions in the right column of Table 3 can be answered with a binary answer, and hence are not open-ended, but one is poorly-posed (e.g. it is difficult to understand Human Interpretation Distribution Entropy vs. Model Distribution Entropy

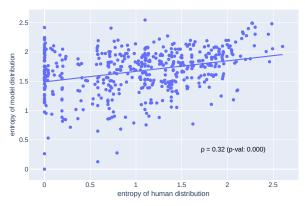

Figure 7: Entropy of human interpretation distribution versus model interpretation distribution on questions in our dataset are positively correlated, indicating that they may be aligned in some cases when choosing interpretations.

# questions	500
total generated interpretations	5715
total deduped interpretations	4680
avg. # generated interpretations	11.5
avg. # deduped interpretations	9.3
total deduplicated interpretations	4680
% gpt-40	55.2
% gemma-2-9b	44.8

Table 2: Dataset statistics for interpretations.

what the user in the top right cell is asking) and the other is not. Subjective questions (a subcategory of open-ended questions) can also be well-posed. As long as an answerer can determine *what* information to include in an answer that would satisfy the information need of the asker (regardless of whether the asker agrees or disagrees with the content), we consider the question well-posed.

		Open-Ended	Not Open-Ended
Poorly-Posed		Why aren't there any positive ill- nesses?	Is it possible to track a child down from their address?
Not Posed	Poorly-	How do people obtain the instrumen- tal tracks of pop songs for karaoke even when those instrumental tracks are not publicly released?	selves for a crime they have been

Table 3: Poorly-posed questions are distinct from openended questions, or those that cannot be answered with a binary response.

B r/NoStupidQuestions

r/NoStupidQuestions is a popular subreddit on the online platform Reddit that encourages users to post questions about any topic, with a few exceptions (e.g. loaded questions or medical questions) There are no particular expertise requirements for answerers.

We choose r/NoStupidQuestions as the backdrop for our study specifically because it is not specific to any topic, besides asking questions. Themed subreddits (i.e r/knitting or r/houseplants) induce richer contexts that can help disambiguate questions which would be harder for models to respond to without that additional contextual information. For example, consider the question "How do you do happy hour?" This question invites many potential interpretations when asked in a (relatively) context-free setting like r/NoStupidQuestions. Potential interpretations include: (1) What types of drinks or foods are typically included in a happy hour? (2) How do restaurants or bars structure happy hour deals or promotions? (3) What are some tips for hosting a happy hour at home?, or (4) *How do different cultures or regions celebrate* happy hour? Consider two different scenarios: (1) this question was asked in r/Alcoholism, and (2) this question was asked in r/InternationalStudents. Learning that these questions were asked in topicspecific subreddits, allows us to suddenly identify very clear dominant interpretations. In the first scenario, a likely interpretation would be "How can individuals in recovery navigate situations involving happy hour without compromising their sobriety?" and in the second scenario, one dominant interpretation would be "Are there cultural norms or etiquette that international students should be aware of when attending happy hour?" r/NoStupidQuestions does not invite any particular bias towards or away from interpretations based on the common ground of subreddit members. r/NoStupidQuestions is similar to r/ELI5 (Fan et al., 2019), a subreddit and dataset that many studies on long-form QA use (e.g. Krishna et al. (2021) or Su et al. (2022).

C Data Filtering

Using the PushShift dump of r/NoStupidQuestions containing posts till 2022,¹² we filter out all posts with (1) deleted titles, (2) titles less than four characters and (3) less than five upvotes. We use surface-form features of post titles to identify questions that are likely to be information-seeking as opposed to community-seeking or other commentary, filtering

out posts with titles that do not contain a question word, those that do not end with a question mark, and those with less than three tokens. These heuristics identify a subset of questions from the Subreddit that may be poorly posed for our study by reducing posts by nearly 92%, leaving 216,089 total posts that survived filtering. We do not include any PII when showing posts to annotators, nor do we plan to release post or user identifiers when releasing the data. All of the posts we consider for annotation are written in English.

Prompt C.1: Asker Reply Classification

Prompt: Community forum websites allows users to ask questions (askers), other users to answer them (answerers), and askers to reply to answerers. When askers reply to answerers, they may indicate whether their question was correctly interpreted, and then answered, by the answerer. Given an asker's reply to an answerer, determine if their question was correctly interpreted and answered (answered), not answered (unanswered), or if their reply is unrelated to whether or not the answerer correctly interpreted their question (unrelated). End your response with [END].

REPLY: {reply}

LABEL:

D Annotator Instructions

D.1 Stage 1: Instructions

When humans formulate questions about topics or content they are unfamiliar with, they can end up posing questions that are unclear, vague, ambiguous, or underspecified. Consider the question: *Can I make my computer "Learn" new unicode symbols?*

In order to answer this question, we might make some assumptions, including about what exactly we believe the asker is really asking. For example, the word "learn" could mean render (e.g. can my computer render new unicode symbols), or it could mean generate (as in, can my computer generate new unicode symbols given a description). Sometimes these assumptions can lead to seamless question answering (a user may ask a poorly posed question, and an answerer makes the necessary inferences to answer well).

However, in some cases, askers may feel an answer to their question falls short if the answerer made incorrect or insufficient assumptions about the intent of the asker. Our goal is to study why questions posed by humans lead to satisfactory or

¹²https://github.com/Watchful1/PushshiftDumps

dissatisfactory answers. To do this, we study interactions between users on Reddit, an online community forum-based platform. Specifically, we study interactions from r/NoStupidQuestions, a subreddit meant to openly ask questions about any topic.

Here, a user makes a post asking a question about a random topic. Sometimes, this question is clear and it is easy to infer the intent of the question, and in turn, answer it. Other times, the question is poorly formed, and it is difficult to understand what the user is asking. Then, a different user will make a comment on the post, trying to respond to the question. It is important to note that in order to answer the question, the answerer makes certain assumptions about the question and the asker, and picks out a likely interpretation of the question to answer. Sometimes this interpretation aligns with the question the user asked, and sometimes it is a departure from what the original asker intended. Your task is to simply identify the interpreted question that the answerer answered. We will show you a user question and a comment containing an answer to the question written by a different user. For example:

[**Original Post**] Can I make my computer "Learn" new unicode symbols?

[Answer] You can't really create your own unicode symbols, you can however submit an idea for future expansions at http://unicode.org/pending/proposals.html

Given a particular post and answer from another user, your task is to rewrite the question to capture what the answerer interpreted the question to be. It is okay to indicate "No Change" if there is strong alignment between the original question and the answerer's interpretation of the question. For example, in the example above, a rewrite may look like: *Can I create or propose new Unicode symbols myself?*

In the event that there is no change in the semantic meaning of the question, but the question itself uses colloquial/informal language or has a certain pragmatic interpretation, please rewrite to eliminate the informal language or make the pragmatic meaning explicit. For example:

[**Original Post**] Why is the enrollment period for insurance even a thing?

[Answer] The reason is so you don't go with cheap/no insurance while you are healthy and then sign up for expensive insurance as soon as you get sick.

[Answerer's Interpretation] Why are there designated enrollment periods for health insurance?

This rewrite removes the informal language "even a thing", as well as makes it clear that the answerer interpreted "insurance" to specifically mean "health insurance".

D.2 Stage 2: Instructions

We provide the same instructions as the first stage, but rephrase the statement of the task as follows: Given a particular post, answer, and a reply from the original poster, your task is to rewrite the question as clearly as possible to capture the intent or additional information expressed in the reply. Your rewrite should eliminate any ambiguity, underspecificity, or vagueness in the original question. It is okay for your rewrite not to be answerable by the answer provided, since, in many cases, the answerer answered a different question than what the original poster intended. For example:

[**Original Post:**] Can I make my computer "Learn" new unicode symbols?

[Answer:] You can't really create your own unicode symbols, you can however submit an idea for future expansions at http://unicode.org/pending/proposals.html.

[Original Poster's Reply:] Create, no, Correctly render existing unicode symbols is what i mean

[**Rewrite:**] How do I install custom unicode symbols on my computer so that I can type custom glyphs and emojis and have my computer correctly render them?

Prompt D.1: Interpretation Generation

Prompt: Users typically try to express a need for information through a **question**. Sometimes, from the language of the **question** alone, it is not clear what their exact information need is. This leads to many distinct interpretations of their **question**, each representing different information needs. You will be given a **question** that may have many distinct interpretations. Output those interpretations as unambiguous questions in a numbered list. Make sure your interpretations are specific and as clear as possible, and are as diverse as possible. If the user's information need is already clear from their question, output 'NONE'. Otherwise, output the numbered list and nothing else.

QUESTION: {question}

Interpretations:

Instruction D.2: Duplicate Question Identification

Instruct: Given a question, identify other duplicate questions.

QUERY: {**query**}

Prompt D.3: Interpretation Support

Instruction: I will give you some context, and a question. Using the context, answer the question with a span from the context. If the question cannot be answered from the context, output NONE. Here are some examples: Context: When you pull the string taut and talk into it your voice makes the string vibrate. The vibrations then travel through the string and into the air inside the receiving can, turning into audible sound waves. Question: How does the tin can telephone work in terms of physics? Answer Span: your voice makes the string vibrate. The vibrations then travel through the string and into the air Context: You can't digest gum it's just the sugar that flavors it Question: Are calories in gum counted even if you spit it out? Answer Span: NONE Context: I'd say it's more of an "honorary" doctor. My sister is in school to become a nurse practitioner, but her degree is technically a doctorate in nursing. She would not call herself a doctor by her standards. Chiropractors are not medical doctors. While they do study they don't go to med advanced kinesiology, school and thus should not be considered a doctor. Unless, someone has a PhD and prefers it. That's the only time outside of an MD that I would call someone Dr. Question: Do patients use the title "doctor" when visiting professional chiropractors? Answer Span: someone has a PhD and prefers it. That's the only time outside of an MD that I would call someone Dr. Context: It's what the British call lines of people. If you're waiting in a line at a supermarket or something, that's a queue. From the dictionary: queue, British, a line or sequence of people or vehicles awaiting their turn to be attended to or to proceed. Question: What is a queue in computer science? Answer Span: NONE

Context: {context}
Question: {question}
Answer Span:

Prompt D.4: Question Answering
Prompt: Answer the following question in 5 sentences or less: {question}

Answer: {a}

E Human-Written Interpretations versus Model-Generated Interpretations

Here, we provide examples of interpretations written by human trivia enthusiasts and model-

generated interpretations. In some cases, humans performed deeper reasoning about why the asker may have posed their question in a particular manner, drawing on their own experiences or on commonsense reasoning. Figure 9 shows three examples from the set of 30 that were annotated by humans.

F Measuring and Validating Poorly-Posedness

Annotators from Section 5.1 are instructed to score each interpretation on a 1-5 scale based on likelihood of matching the asker's information need. The scores are designed to be calibrated across the interpretations provided for the question: interpretations that the annotator felt better matched the asker's information need received higher scores. If all interpretations seemed equally likely, scores reflected that uniformity. For example, if annotators felt all interpretations were equally unlikely to match the original question asker's information need, they gave a score of 1 or 2 to all interpretations. For example, if all interpretations seemed unlikely, annotators gave scores of 1 or 2 to all; if most seemed to match, all received high scores.¹³ Here, we explain the intuition behind our choice of scoring function to convert the rating vector of Likert scores for a question to a number that allows us to quantitatively compare the ambiguity (ill-posed nature) of questions.

Given a list of human ratings of interpretations, well-posed questions should have a small number of interpretations with high Likert scores, ideally just one. For instance, in the ideal case, the rating vector of [1, 1, 1, 1, 5] indicates one wellmatched interpretation of the question, with others poorly matched. Conversely, a rating vector of [3, 3, 3, 3, 3] suggests all interpretations are *possi*ble, but no clear preference emerges. Similarly, a rating vector of [5, 5, 5, 5, 1] indicates many wellmatched interpretations, maintaining ambiguity about the asker's information need. These examples illustrate that any metric function that computes a score of ill-posed-ness should meet the following requirements: (1) accept a vector of Likert scores (or in the case of Reddit threads, counts representing the number of answers addressing the interpretation), (2) return a high value when there are no good matches (e.g., [1, 2, 1, 2, 3]), or many

¹³We considered probability assignments or pairwise comparisons, but felt the 1-5 scale was most natural.

Comparison of Original Question/Reply-Informed Rewrite & Dominant Interpretation Cosine Similarities

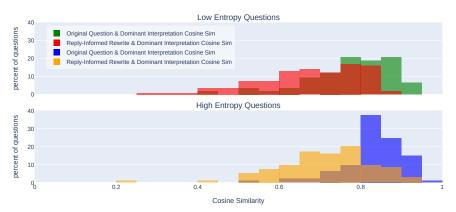

Figure 8: Distance between original question and the dominant interpretation chosen by humans on the post thread and distance between reply-informed rewrite from Stage 2 of annotations and dominant interpretation for both low entropy (top) and high entropy questions (bottom).

good matches (e.g., [5, 5, 5, 1, 5]), and (3) return a low value when there are a small number of very good matches (ideally one), e.g.,: [1, 1, 1, 1, 5].

While there are a many ways to construct a metric function to achieve the three desiderata above, we choose one particular technique as a quantitative means to operationalize our definition of a poorly posed question. Our technique has two steps: 1) normalization, and 2) aggregation. We will now discuss the intuition behind the two steps of our technique to compute our metric, and our choice of mathematical operators: (1) normalization with softmax, (2) aggregation using entropy.

Normalization. First, we want to assign an amount of goodness (mass) to an interpretation based on how *unique* it is in its goodness. If we normalize every question to have a total mass of 1, then a question with only one good interpretation should have most of this mass concentrated on it. Alternatively, a question with many good interpretations should have the mass distributed uniformly across them. One could use many different normalization techniques: L_1 , L_n , or Softmax (with or without a temperature variable). L_n or Softmax normalization accentuates the difference between high scoring interpretations and low scoring ones, whereas L1 or Softmax with a high temperature minimizes such differences. We find that the choice of normalization does not alter our findings, and so we pick softmax for illustrative purposes.

Aggregation. Here, we want to compute a single scalar score from this normalized vector to assign a low score when most of the mass was concentrated in a small number of interpretations (ideally one),

and a high score when that mass was more diffused. Again, while there are a number of ways to construct such a function, we choose entropy since it is a well known way to determine if most of the mass is concentrated in a small number of options.

G Model Infrastructure

All experiments were run on two NVIDIA RTX A6000s. Models greater than 11B parameters were run using 4 bit quantization.

Question	Human-Written Interpretations	Model-Generated Interpretation Space
Do doctors (M.D., D.O, etc.) work outside their specialty under any circumstance?	 Do hospitals limit when and how doctors can work outside of their specialty? Do insurance companies limit payment for specialties to doctors trained in that area? Do doctors trained in one specialty have the skills to work outside of that specialty? Why won't my (x specialty doctor) do (thing I want that y specialty doctors do)? If I am studying (X branch of medicine), will I still be allowed to do (y thing I enjoy doing)? Do doctors have knowledge outside of their specialties? When can I trust my doctor? 	 Are doctors (M.D., D.O., etc.) legally allowed to work outside their specialty in emergency situations? (2) Can doctors (M.D., D.O., etc.) choose to work outside their specialty if they have additional training or certification in another area? (3) Do doctors (M.D., D.O., etc.) ever work outside their specialty due to staffing shortages or in rural area? (4) Are there any regulations or guidelines that permit doctors (M.D., D.O., etc.) to practice outside their specialty in certain healthcare settings? (5) How often do doctors (M.D., D.O., etc.) work outside their specialty in practice, and what are the common reasons for doing so? (6) Can a doctor with specialists in, for example, cardiology, ever perform surgery? (7) Do doctors ever collaborate with specialists outside their own area of expertise? (8) Are there instances where a doctor might be required to provide care outside their speciality? (9) Is it common for doctors to work in multidisciplinary teams that involve other specialites? (9) Los a doctor with a medical degree work in a general practice setting, even if they have specialized training?
Is it illegal to refuse to treat your sick child?	 Can parents be arrested if their kid is sick and they don't go to a hospital? What religious exemptions exist for not treating a child? Can I use medicinal practices from my culture/belief system rather than state-prescribed medicinal practices? How much legal authority do parents have over their children's bodily autonomy? Who gets to decide in the case of a medical dispute between a parent and a child? 	 (1) Is it illegal for parents to refuse medical treatment for their sick child in the state of California? (2) Is it illegal for parents to refuse medical treatment for their sick child in the United Kingdom? (3) Are there any laws that prohibit parents from refusing medical treatment for their sick children? (4) What are the legal consequences for a parent who refuses to seek medical treatment for their sick child? (5) In what situations is it legally permissible for a parent to refuse medical treatment for their sick child? (6) Are there any exceptions to the legal requirement for parents to provide medical treatment to their sick child? (7) What are the ethical considerations surrounding a parent's right to refuse medical treatment for their sick child?
Why don't cashiers just have chairs?	 (1) Why don't cashiers sit in chairs when they perform their job? (2) Why do cashiers perform their job standing? (3) What cultural practices causes cashiers to stand? (4) Why does only (store x) allow their cashiers to sit? 	 (1) What are the ergonomic or health reasons for cashiers not having chairs? (2) Are there any legal or regulatory reasons that prevent cashiers from having chairs? (3) How does the absence of chairs for cashiers affect their job performance or customer service? (4) What are the historical reasons for cashiers not having chairs in stores? (5) Are there any stores or countries where cashiers are provided with chairs, and if so, why? (6) What are the financial implications for businesses if they were to provide chairs for cashiers? (7) How do cashiers feel about not having chairs, and what are their opinions on this matter? (8) What are the potential benefits and drawbacks of providing chairs for cashiers? (9) Do customers prefer interacting with cashiers who are standing or sitting? (10) Is there a cost-effectiveness analysis regarding the provision of chairs for cashiers? (11) What are the ergonomic considerations for cashier workstations, and how do they relate to the use of chairs?
