CSMC 412

Operating Systems Prof. Ashok K Agrawala

Set 17

File-System Interface

- File Concept
- Access Methods
- Disk and Directory Structure
- File-System Mounting
- File Sharing
- Protection

Objectives

- To explain the function of file systems
- To describe the interfaces to file systems
- To discuss file-system design tradeoffs, including access methods, file sharing, file locking, and directory structures
- To explore file-system protection

File Concept

- Contiguous logical address space
 - Records
- Types:
 - Data
 - numeric
 - character
 - binary
 - Program
- Contents defined by file's creator
 - Many types
 - Consider text file, source file, executable file

File Attributes

- Name only information kept in human-readable form
- Identifier unique tag (number) identifies file within file system
- **Type** needed for systems that support different types
- Location pointer to file location on device
- **Size** current file size
- Protection controls who can do reading, writing, executing
- Time, date, and user identification data for protection, security, and usage monitoring
- Information about files are kept in the directory structure, which is maintained on the disk
- Many variations, including extended file attributes such as file checksum
- Information kept in the directory structure

File info Window on Mac OS X

File Operations

- File is an abstract data type
- Create
- Write at write pointer location
- Read at read pointer location
- Reposition within file seek
- Delete
- Truncate
- Open(F_i) search the directory structure on disk for entry F_i, and move the content of entry to memory
- Close (F_i) move the content of entry F_i in memory to directory structure on disk

Open Files

- Several pieces of data are needed to manage open files:
 - Open-file table: tracks open files
 - File pointer: pointer to last read/write location, per process that has the file open
 - File-open count: counter of number of times a file is open to allow removal of data from open-file table when last processes closes it
 - Disk location of the file: cache of data access information
 - Access rights: per-process access mode information

Open File Locking

- Provided by some operating systems and file systems
 - Similar to reader-writer locks
 - Shared lock similar to reader lock several processes can acquire concurrently
 - Exclusive lock similar to writer lock
- Mediates access to a file
- Mandatory or advisory:
 - Mandatory access is denied depending on locks held and requested
 - Advisory processes can find status of locks and decide what to do

File Locking Example – Java API

```
import java.io.*;
import java.nio.channels.*;
public class LockingExample {
   public static final boolean EXCLUSIVE = false;
   public static final boolean SHARED = true;
   public static void main(String arsg[]) throws IOException {
              FileLock sharedLock = null;
              FileLock exclusiveLock = null;
              try {
                            RandomAccessFile raf = new RandomAccessFile("file.txt", "rw");
                           // get the channel for the file
                            FileChannel ch = raf.getChannel();
                           // this locks the first half of the file - exclusive
                            exclusiveLock = ch.lock(0, raf.length()/2, EXCLUSIVE);
                            /** Now modify the data . . . */
                           // release the lock
```

```
exclusiveLock.release();
```

File Locking Example – Java API (Cont.)

```
// this locks the second half of the file - shared
            sharedLock = ch.lock(raf.length()/2+1, raf.length(),
            /** Now read the data . . . */
            // release the lock
            sharedLock.release();
} catch (java.io.IOException ioe) {
            System.err.println(ioe);
finally {
            if (exclusiveLock != null)
            exclusiveLock.release();
            if (sharedLock != null)
            sharedLock.release();
```

SHARED);

File Name

- <u>name</u> used to uniquely identify a <u>computer file</u> stored in a <u>file</u> <u>system</u>.
- Name may include:
 - Host
 - Device
 - Path/Directory/Folder
 - File base name
 - Type/Extension
 - Version
- Common names:

| File Name | Contents |
|--------------|-----------------------------------------------|
| README | Project overview |
| MANIFEST | List of project files with brief explanations |
| INSTALL | Installation instructions |
| Copying | Licensing information |
| TODO | Wish list for future extensions |
| NEWS | Documentation on user-visible changes |
| Changes | Code change summary |
| configure | Platform configuration script |
| Makefile | Build specification |
| Makefile.SH | Shell script producing the above |
| config.h | Platform configuration definitions |
| config_h.SH | Shell script producing the above |
| patchlevel.h | Defines the project release version |

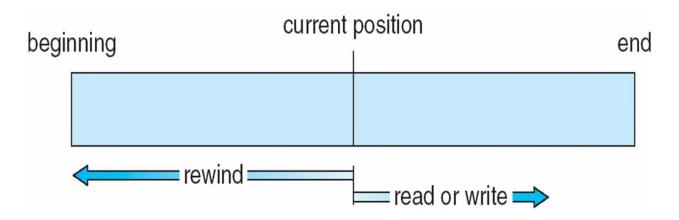

File Types – Name, Extension

| file type | usual extension | function |
|----------------|-----------------------------|------------------------------------------------------------------------------------------------|
| executable | exe, com, bin or none | ready-to-run machine- language program |
| object | obj, o | compiled, machine language, not linked |
| source code | c, cc, java, pas, asm, a | source code in various languages |
| batch | bat, sh | commands to the command interpreter |
| text | txt, doc | textual data, documents |
| word processor | wp, tex, rtf, doc | various word-processor formats |
| library | lib, a, so, dll | libraries of routines for programmers |
| print or view | ps, pdf, jpg | ASCII or binary file in a format for printing or viewing |
| archive | arc, zip, tar | related files grouped into one file, sometimes com- pressed, for archiving or storage |
| multimedia | mpeg, mov, rm, mp3, avi | binary file containing audio or A/V information |

File Structure

- None sequence of words, bytes
- Simple record structure
 - Lines
 - Fixed length
 - Variable length
- Complex Structures
 - Formatted document
 - Relocatable load file
- Can simulate last two with first method by inserting appropriate control characters
- Who decides:
 - Operating system
 - Program

Sequential-access File

Access Methods

• Sequential Access

- Direct Access file is fixed length logical records
 - read n
 write n
 position to n
 read next
 write next
 rewrite n

n = relative block number

• Relative block numbers allow OS to decide where file should be placed

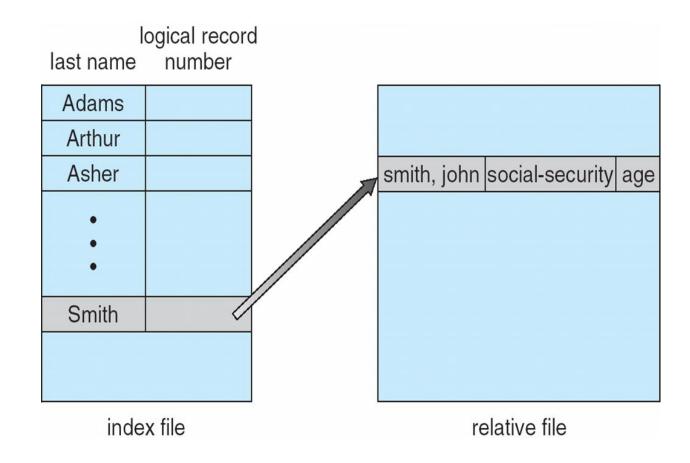

Simulation of Sequential Access on Direct-access File

| sequential access | implementation for direct access |
|-------------------|--------------------------------------------------------|
| reset | cp=0; |
| read next | <i>read cp</i> ; <i>cp</i> = <i>cp</i> + 1 ; |
| write next | write cp ; cp = cp + 1; |

Other Access Methods

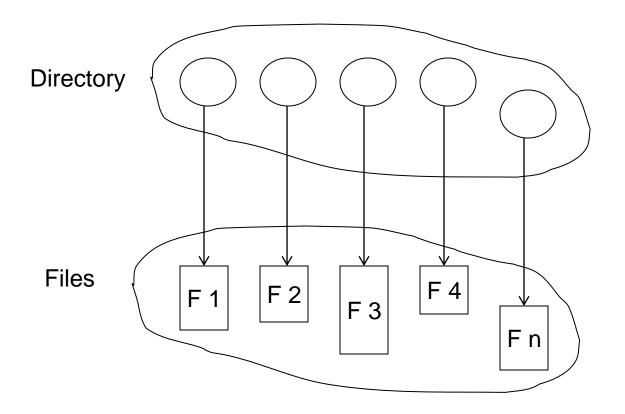

- Can be built on top of base methods
- General involve creation of an index for the file
- Keep index in memory for fast determination of location of data to be operated on (consider UPC code plus record of data about that item)
- If too large, index (in memory) of the index (on disk)
- IBM indexed sequential-access method (ISAM)
 - Small master index, points to disk blocks of secondary index
 - File kept sorted on a defined key
 - All done by the OS
- VMS operating system provides index and relative files as another example (see next slide)

Example of Index and Relative Files

Directory Structure

• A collection of nodes containing information about all files

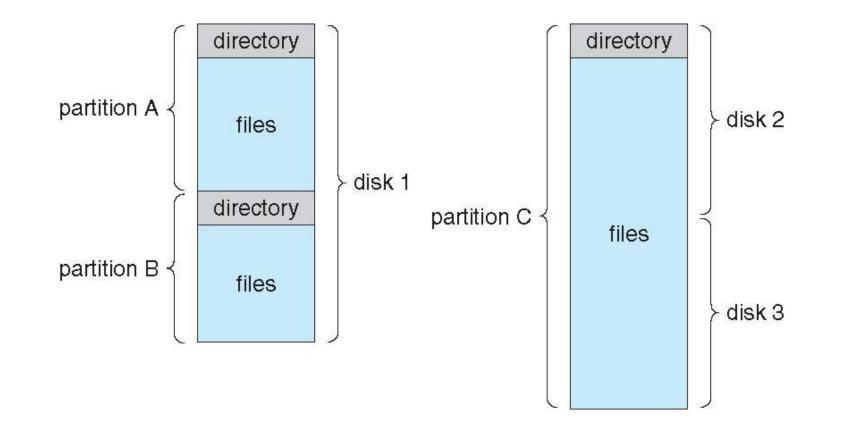

Both the directory structure and the files reside on disk

Disk Structure

- Disk can be subdivided into partitions
- Disks or partitions can be **RAID** protected against failure
- Disk or partition can be used raw without a file system, or formatted with a file system
- Partitions also known as minidisks, slices
- Entity containing file system known as a volume
- Each volume containing file system also tracks that file system's info in device directory or volume table of contents
- As well as general-purpose file systems there are many special-purpose file systems, frequently all within the same operating system or computer

A Typical File-system Organization

Types of File Systems

- We mostly talk of general-purpose file systems
- But systems frequently have may file systems, some general- and some special- purpose
- Consider Solaris has
 - tmpfs memory-based volatile FS for fast, temporary I/O
 - objfs interface into kernel memory to get kernel symbols for debugging
 - ctfs contract file system for managing daemons
 - lofs loopback file system allows one FS to be accessed in place of another
 - procfs kernel interface to process structures
 - ufs, zfs general purpose file systems

Operations Performed on Directory

- Search for a file
- Create a file
- Delete a file
- List a directory
- Rename a file
- Traverse the file system

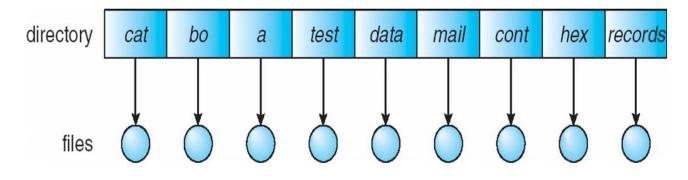

Directory Organization

The directory is organized logically to obtain

- Efficiency locating a file quickly
- Naming convenient to users
 - Two users can have same name for different files
 - The same file can have several different names
- Grouping logical grouping of files by properties, (e.g., all Java programs, all games, ...)

Single-Level Directory

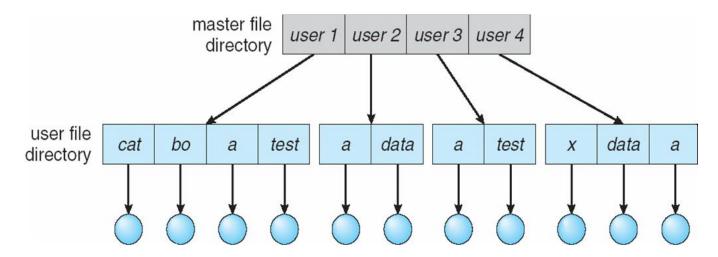

• A single directory for all users

- Naming problem
- Grouping problem

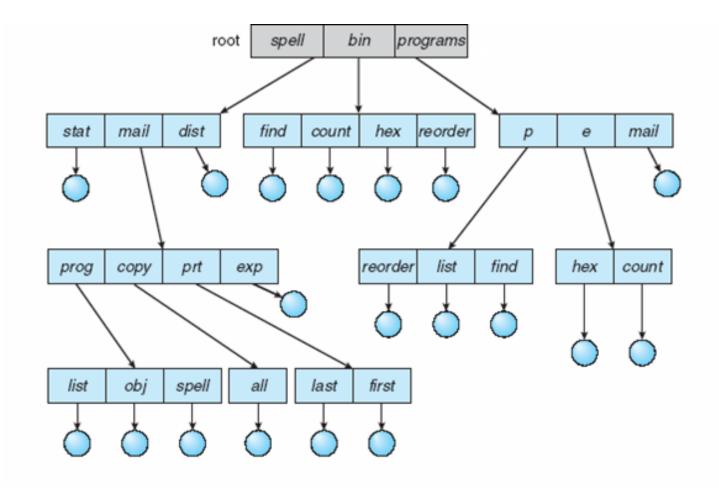

Two-Level Directory

• Separate directory for each user

- Path name
- Can have the same file name for different user
- Efficient searching
- No grouping capability

Tree-Structured Directories

Tree-Structured Directories (Cont.)

- Efficient searching
- Grouping Capability
- Current directory (working directory)
 - cd /spell/mail/prog
 - type list

Tree-Structured Directories (Cont)

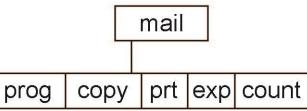

- Absolute or relative path name
- Creating a new file is done in current directory
- Delete a file

rm <file-name>

• Creating a new subdirectory is done in current directory mkdir <dir-name>

Example: if in current directory /mail

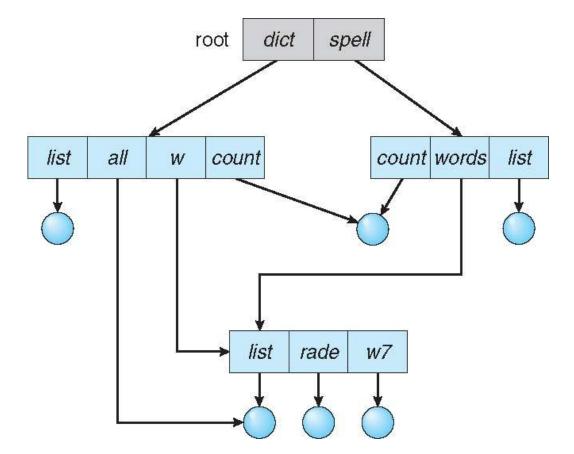

mkdir count

Deleting "mail" \Rightarrow deleting the entire subtree rooted by "mail"

Acyclic-Graph Directories

• Have shared subdirectories and files

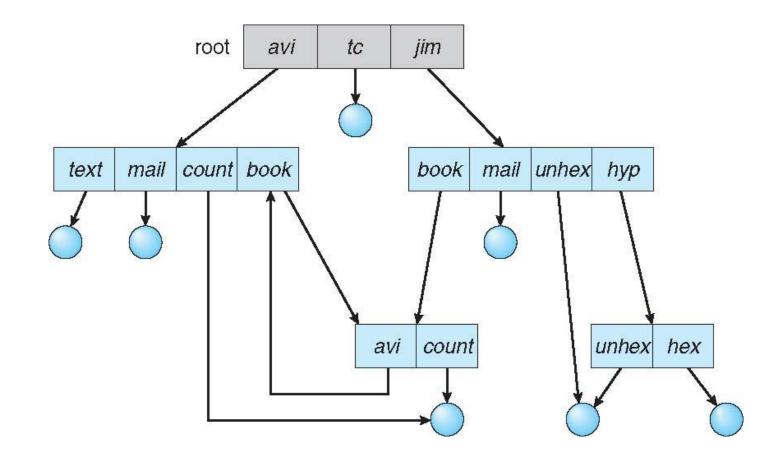

Acyclic-Graph Directories (Cont.)

- Two different names (aliasing)
- If *dict* deletes $list \Rightarrow$ dangling pointer

Solutions:

- Backpointers, so we can delete all pointers Variable size records a problem
- Backpointers using a daisy chain organization
- Entry-hold-count solution
- New directory entry type
 - Link another name (pointer) to an existing file
 - **Resolve the link** follow pointer to locate the file

General Graph Directory

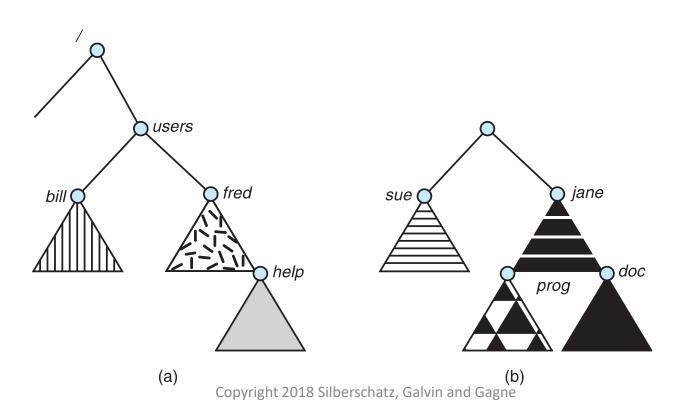

General Graph Directory (Cont.)

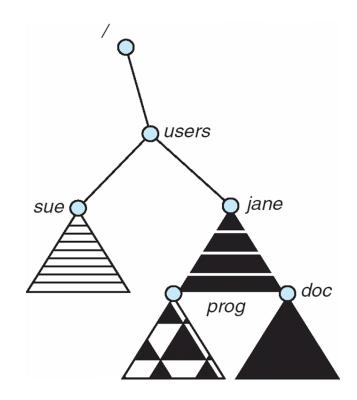

- How do we guarantee no cycles?
 - Allow only links to file not subdirectories
 - Garbage collection
 - Every time a new link is added use a cycle detection algorithm to determine whether it is OK

File System Mounting

- A file system must be mounted before it can be accessed
- A unmounted file system is mounted at a mount point

Mount Point

File Sharing

- Sharing of files on multi-user systems is desirable
- Sharing may be done through a protection scheme
- On distributed systems, files may be shared across a network
- Network File System (NFS) is a common distributed file-sharing method
- If multi-user system
 - User IDs identify users, allowing permissions and protections to be per-user Group IDs allow users to be in groups, permitting group access rights
 - Owner of a file / directory
 - Group of a file / directory

File Sharing – Remote File Systems

- Uses networking to allow file system access between systems
 - Manually via programs like FTP
 - Automatically, seamlessly using distributed file systems
 - Semi automatically via the world wide web
- Client-server model allows clients to mount remote file systems from servers
 - Server can serve multiple clients
 - Client and user-on-client identification is insecure or complicated
 - NFS is standard UNIX client-server file sharing protocol
 - **CIFS** is standard Windows protocol
 - Standard operating system file calls are translated into remote calls
- Distributed Information Systems (distributed naming services) such as LDAP, DNS, NIS, Active Directory implement unified access to information needed for remote computing

File Sharing – Failure Modes

- All file systems have failure modes
 - For example corruption of directory structures or other non-user data, called metadata
- Remote file systems add new failure modes, due to network failure, server failure
- Recovery from failure can involve state information about status of each remote request
- Stateless protocols such as NFS v3 include all information in each request, allowing easy recovery but less security

File Sharing – Consistency Semantics

- Specify how multiple users are to access a shared file simultaneously
 - Similar to process synchronization algorithms
 - Tend to be less complex due to disk I/O and network latency (for remote file systems
 - Andrew File System (AFS) implemented complex remote file sharing semantics
 - Unix file system (UFS) implements:
 - Writes to an open file visible immediately to other users of the same open file
 - Sharing file pointer to allow multiple users to read and write concurrently
 - AFS has session semantics
 - Writes only visible to sessions starting after the file is closed

Protection

- File owner/creator should be able to control:
 - what can be done
 - by whom
- Types of access
 - Read
 - Write
 - Execute
 - Append
 - Delete
 - List

Access Lists and Groups

- Mode of access: read, write, execute
- Three classes of users on Unix / Linux

| | | | RWX | erroren energia errolatio |
|-------------------------|---|---------------|-----|---------------------------|
| a) owner access | 7 | \Rightarrow | 111 | owner group public |
| | | | RWX | |
| b) group access | 6 | \Rightarrow | 110 | |
| | | | RWX | chmod 761 game |
| c) public access | 1 | \Rightarrow | 001 | |

- Ask manager to create a group (unique name), say G, and add some users to the group.
- For a particular file (say *game*) or subdirectory, define an appropriate access.

Attach a group to a file

Windows 7 Access-Control List Management
