

Introduction

- Class is an introduction to parallel computing
 - topics include: hardware, applications, compilers, system software, and tools
- Will count for Masters/PhD Comp Credit
- Work required
 - small programming assignment
 - midterm
 - classroom participation
 - project
- Photos will taken of the class to help me learn names

What is Parallel Computing?

- Does it include:

- super-scalar processing (more than one insn at once)?
- client/server computing?
 - what if RPC calls are non-blocking?
- vector processing (same instruction to several values)?
- collection of PC's **not** connected to a network?

- For this class, parallel computing is:

- a collection of processing elements (more than one).
- connected to a communication network.
- working together to solve a single problem.

Why Parallelism

- Speed

- need to get results faster than possible with sequential
 - a weather forecast that is late is useless
- could come from
 - more processing elements (P.E.)
 - more memory size
 - more disks

- Cost: cheaper to buy many smaller machines

- this is only recently true due to
 - VLSI
 - commodity parts

What Does a Parallel Computer Look Like?

- Hardware
 - processors
 - communication
 - memory
 - coordination
- Software
 - languages
 - operating systems
 - programming models

Processing Elements (PE)

- Key Processor Choices

- How many?
- How powerful?
- Custom or off-the-shelf?

- Major Styles of Parallel Computing

- SIMD - Single Instruction Multiple Data
 - one master program counter
- MIMD - Multiple Instruction Multiple Data
 - separate code for each processor
- SPMD - Single Program Multiple Data
 - same code on each processor, separate PC's on each
- Dataflow - instruction waits for operands
 - “automatically” finds parallelism

Communication Networks

- Connect
 - PE's, memory, I/O
- Key Performance Issues
 - latency: time for first byte
 - throughput: average bytes/second
- Possible Topologies
 - bus - simple, but doesn't scale

- ring - orders delivery of messages

Topologies (cont)

- tree - needs to increase bandwidth near the top

- mesh - two or three dimensions

- hypercube - needs a power of number of nodes

Memory Systems

- Key Performance Issues

- latency: time for first byte
- throughput: average bytes/second

- Design Issues

- Where is the memory
 - divided among each node
 - centrally located (on communication network)
- Access by processors
 - can all processors get to all memory?
 - is the access time uniform?

Coordination

- Synchronization
 - protection of a single object (locks)
 - coordination of processors (barriers)
- Size of a unit of work by a processor
 - need to manage two issues
 - load balance - processors have equal work
 - coordination overhead - communication and sync.
 - often called “grain” size - large grain vs. fine grain
